# New Algorithm DOM for Graph Coloring by Domination Covering 

## Basic Definitions

Definition 1. Node A in the incompatibility graph covers node B if

1) $A$ and $B$ have no common edges;
2) $A$ has edges with all the nodes that $B$ has edges with;
3) $A$ has at least one more edge than $B$.

# New Algorithm DOM for Graph Coloring by Domination Covering 

## Basic Definitions (cont'd)

Definition 2. If conditions 1) and 2 ) are true and $A$ and $B$ have the same number of nodes, then it is called pseudo-covering.
Definition 3. The complete graph is one in which all the pairs of vertices are connected.
Definition 4. A non-reducible graph is a graph that is not complete and has no covered or pseudo-covered nodes. Otherwise, the graph is reducible.

Theorem 1. If any node $A$ in the incompatibility graph covers any other node $B$ in the graph, then node B can be removed from the graph, and in a pseudo-covering any one of the nodes $A$ and $B$ can be removed.

Theorem 2. If a graph is reducible and can be reduced to a complete graph by successive removing of all its covered and pseudo-covered nodes, then Algorithm DOM finds the exact coloring (coloring with the minimum number of colors).

## Example Showing How DOM Colors a Redlucible Giraph

Step 1: Removing 2 and 7 covered by 1
Step 2: Removing 5 covered by 4

## Example Showing How DOM Colors of a Reducible Graph

Step 3: Coloring the complete graph Step 4: Coloring the covered vertices

Example Showing How DOM Colors of a Non-Reducible Graph

Step 1: Removing random node (1)
Step 2: Removing 2 and 6 covered by 4
Step 3: Removing 3 pseudo-covered by 5

Example Showing How DOM Colors of a Reducible Graph

Step 4: Coloring the complete graph
Step 5: Coloring the remaining nodes

## Other Topics = Review

## Definition of a Cartesian Product <br> Definition of a Relation as a subset of Cartesian Product

Oriented and non-oriented relations
Characteristic function of a relation

This to be covered only if students do not have background!

# More on combinatorial 

 problems- Graph coloring applied to SOP minimization What is a relation and characteristic function coloring and other machines based on circuits -satisfiability/Petrick machines

## What have we learnt?

Finding the minimum column multiplicity for a bound set of variables is an important problem in Curtis decomposition.

We compared two graph-coloring programs: one exact, and other one based on heuristics, which can give, however, provably exact results on some types of graphs.

These programs were incorporated into the multi-valued decomposer MVGUD, developed at Portland State University.

## What have we learned (cont)

We proved that the exact graph coloring is not necessary for high-quality decomposers.

We improved by orders of magnitude the speed of the column multiplicity problem, with very little or no sacrifice of decomposition quality.

Comparison of our experimental results with competing decomposers shows that for nearly all benchmarks our solutions are best and time is usually not too high.

## What have we learnt (cont)

Developed a new algorithm to create incompatibility graphs

Presented a new heuristic dominance graph coloring program DOM

Proved that exact graph coloring algorithm is not needed

Introduced early filtering of decompositions
Shown by comparison that this approach is faster and gives better decompositions

## What you have to remember

How to decompose any single or multiple output Boolean function or relation using both Ashenhurst and Curtis decomposition

How to do the same for multi-valued function or relation

How to color graphs efficiently and how to write a LISP program for coloring
